1. Introduction

Consider the following unconstrained optimization objective function;

\[
\min \left\{ f(x) : x \in \mathbb{R}^n \right\}
\]

(1)

where \( f : \mathbb{R}^n \rightarrow \mathbb{R} \) is a continuously differentiable function. \( \mathbb{R}^n \) is denoted as \( n \)-dimensional Euclidean space [1]. With any \( x_0 \in \mathbb{R}^n \) as an initial guess, generally, a sequence of \( \{ x_k \} \) is generated by employing the CG iterative method given by;

\[
x_{k+1} = x_k + \alpha_k d_k, \quad k = 0,1,2,\ldots
\]

(2)

where \( x_k \) is the \( k^{th} \) iterative point and \( \alpha_k > 0 \) is a step size while the search direction \( d_k \) is defined by;

\[
d_k = \begin{cases} 
-g_k & \text{if } k = 0 \\
-g_k + \beta_k d_{k-1} & \text{if } k \geq 1
\end{cases}
\]

(3)

The scalar \( \beta_k \) is called the CG coefficient and \( g_k \) is the gradient of \( f \) at point \( x_k \). Step size \( \alpha_k > 0 \) is the stepsize determined by using exact line search, given as;

\[
f(x_k + \alpha_k d_k) = \min_{\alpha \geq 0} f(x_k + \alpha d_k).
\]

ARTICLE INFO

ABSTRACT

One of the popular approaches in modifying the Conjugate Gradient (CG) Method is hybridization. In this paper, a new hybrid CG is introduced and its performance is compared to the classical CG method which are Rivaie-Mustafa-Ismail-Leong (RMIL) and Syarafina-Mustafa-Rivaie (SMR) methods. The proposed hybrid CG is evaluated as a convex combination of RMIL and SMR method. Their performance are analyzed under the exact line search. The comparison performance showed that the hybrid CG is promising and has outperformed the classical CG of RMIL and SMR in terms of the number of iterations and central processing unit per time.

This is an open access article under the CC–BY-SA license.
Exact line search is used because of its well-known ability to provide the optimal step size [2]. Recently, studies have shown that the newer technologies with faster processors and better equipment have successfully eliminated the speed problems often suffered by exact line search, as demonstrated by Rivai et al. [1]. This motivates plenty of its applications for solving unconstrained optimization problems. From [3], [4], a classical CG method introduced were;

$$\beta_{k}^{RMIL} = \frac{g_{k}^{T}(g_{k} - g_{k-1})}{\|d_{k-1}\|^{2}} \quad (5)$$

$$\beta_{k}^{SMR} = \max \left\{ 0, \frac{\|g_{k}\|^{2} - \|g_{k}^{T}g_{k-1}\|}{\|d_{k-1}\|^{2}} \right\} \quad (6)$$

where the $g_{k}$ and $g_{k-1}$ are the abbreviations of $g(x_{k})$ and $g(x_{k-1})$. They are the gradients of $f(x)$ at points $x_{k}$ and $x_{k-1}$ respectively. Euclidean norm of the vectors is denoted by $\|\|$. These corresponding methods are known as RMIL (Rivai–Mustafa–Ismail–Leong) [3] and SMR (Syarafina–Mustafa–Rivai) [4]. Different CG method yield different performance of the CG algorithm due to the different choices for calculating the CG coefficients. Some well known CG formulas are;

$$\beta_{k}^{HS} = \frac{g_{k}^{T}(g_{k} - g_{k-1})}{(g_{k} - g_{k-1})^{T}d_{k-1}} \quad (7)$$

$$\beta_{k}^{FR} = \frac{g_{k}^{T}g_{k}}{\|g_{k-1}\|^{2}} \quad (8)$$

$$\beta_{k}^{PRP} = \frac{g_{k}^{T}(g_{k} - g_{k-1})}{\|g_{k-1}\|^{2}} \quad (9)$$

$$\beta_{k}^{CD} = -\frac{g_{k}^{T}g_{k}}{d_{k-1}^{T}g_{k}} \quad (10)$$

$$\beta_{k}^{DY} = \frac{g_{k}^{T}g_{k}}{(g_{k} - g_{k-1})^{T}d_{k-1}} \quad (11)$$

$$\beta_{k}^{LS} = \frac{g_{k}^{T}(g_{k} - g_{k-1})}{-d_{k-1}^{T}g_{k}} \quad (12)$$

These corresponding methods are known as HS (Hestenes and Steifel [5]), FR (Fletcher and Reeves [6]), PRP (Polak and Ribiere [7]), CD (Conjugate Descent by Fletcher [8]), DY (Dai and Yuan [9]), and LS (Liu–Storey [10]), respectively. Due to the strictly convex quadratic function $f(x)$, all of these methods (7–12) have finite convergence properties under exact line search. From all the mentioned methods, CG coefficient in (8), (10) and (11) have strong convergence properties but not excellent in practical performance due to the jamming problem. Meanwhile, methods in (7), (9) and (12) have better numerical performance though lacking in convergence properties [11]. Conjugate gradient method can be classified into three different groups; classical, scaled, and hybrid CG method [12]. Methods mentioned in (7–12) are called classical CG due to their simple approaches. Detailed discussions are available in [13]–[24]. Meanwhile, some well known hybrid conjugate algorithms are;

$$\beta_{k}^{HDY} = \max\{0, \min\{\beta_{k}^{HS}, \beta_{k}^{DY}\}\}$$

(13)
\[ \beta_{k}^{HUS} = \max \{ 0, \min \{ \beta_{k}^{PRP}, \beta_{k}^{FR} \} \} \]  
\[ \beta_{k}^{HLSCD} = \max \{ 0, \min \{ \beta_{k}^{LS}, \beta_{k}^{CD} \} \} \]  
\[ \beta_{k}^{HHH} = \frac{\|g_{k}\|^2 - \max \{ 0, \frac{\|g_{k}\|}{\|g_{k-1}\|} g_{k}^{T} g_{k-1} \}}{\max \{ \|g_{k-1}\|^2, d_{k-1}^{T} (g_{k} - g_{k-1}) \}} \]  

From (13)-(16) HDY is a modification effort from Dai and Yuan [9] combining its algorithm with Hestenes and Steifel [5], HUS was introduced by Hu and Storey, HLSCD is the combination of LS [10] and CD [8], and HJHJ is a hybrid CG from Jinbao-Han-Jiang [25]. In this paper, the main objective is to compare the performance of classical and hybrid CG methods. The idea is to combine different conjugate algorithms to use the projections to form a new hybrid convex combination algorithm in order to avoid jamming [11] and compare with the original coefficients used for its hybridization. Hence SMR and RMIL are combined in order to introduce a hybrid CG and its performance is compared between SMR and RMIL. SMR has good computational properties while RMIL has strong convergence properties [1], [2] both under exact line search. The combinations of all the good criteria of SMR and RMIL are used in order to obtain a better practical algorithm both in numerical and convergence analysis. Section two will discuss the motivation of the algorithm and the new hybrid conjugate gradient algorithm. Section three presents the convergence analysis. Numerical experiments are discussed in section four, and the last section concludes all the works in this paper.

2. Method

Hybrid-Syarafina-Mustafa-Rivaie (HSMR) method is the idea of combining SMR and RMIL methods together. HSMR method is introduced as Hybrid-Syarafina-Mustafa-Rivaie method and is known as:

\[ \beta_{k}^{HSMR} = \max \{ 0, \min \{ \beta_{k}^{SMR}, \beta_{k}^{RMIL} \} \} \]  

The idea was initiated by using the restart strategy proposed in Jinbao et al. [25]. If the value tends to be negative values, it is preferable to set \( \beta_{k} = 0 \), which implies a restart along \( g_{k} \). If \( \beta_{k} < 0 \), the search direction \( d_{k} \) from (3) tend to almost opposite to \( d_{k-1} \). Then, the conjugate gradient (CG) coefficient to \( \beta_{k} > 0 \), the two consecutive search directions are prevented from tending to be almost opposite [26]. The new algorithm of \( \beta_{k}^{HSMR} \) is given as in Algorithm 1 (Fig. 1).

Algorithm 1: Conjugate gradient method

Step 1: Initialization. Set \( k = 0 \) and select \( x_{0} \in \mathbb{R}^{n} \), \( d_{0} = -g_{0} \), if \( g_{0} = 0 \), stop.

Step 2: Compute \( \beta_{k}^{HSMR} \) based on (17).

Step 3: Compute search directions \( d_{k} \) based on (3). If \( \|g_{k}\| \leq \varepsilon \), then stop.

Otherwise, go to the next step.

Step 4: Compute for \( \alpha_{k} \) based on exact line search (4).

Step 5: Updating new initial point using (2).

Step 6: Convergence test and stopping criteria. If \( f(x_{k+1}) < f(x_{k}) \) and \( \|g_{k}\| \leq \varepsilon \) then, stop.

Otherwise go to Step 2 with \( k = k + 1 \).

Fig. 1. Conjugate gradient algorithm
3. Results and Discussion

3.1. Convergence Analysis

In this section, the convergence analysis for HSMR based on exact line search in (4) is analysed. An algorithm has to possess both sufficient descent condition and global convergence properties for a method to be converged in order to have a good practical algorithm. The convergence analysis for SMR and RMIL can be reached out in Rivai et al. [3] and Mohamed et al. [4].

3.1.1. Sufficient Descent Condition

Sufficient descent condition holds when

\[ g_k^T d_k \leq -C\|g_k\|^2 \quad \text{for} \quad k \geq 0 \quad \text{and} \quad C > 0 \]  

(18)

**Theorem 1:** Consider a CG method with search direction (3) and \( \beta_k^{HSMR} \) defined as (17), then, condition (18) will hold for all \( k \geq 0 \).

**Proof:** From (3), know that \( g_k^T d_0 = -C\|g_0\|^2 \). Hence, condition (18) holds. In order to show condition (18) also hold for \( k \geq 1 \), multiply (3) by \( g_k^T \). Then,

\[ g_k^T d_k = -g_k^T g_k + \beta_k^{HSMR} g_k^T d_{k-1} = -\|g_k\|^2 + \beta_k^{HSMR} g_k^T d_{k-1}. \]  

(19)

For \( k = 1 \), it is easy to know that \( g_1^T d_1 = -\|g_1\|^2 < 0 \). Assume that \( g_k^T d_{k-1} < 0 \) holds for \( k-1 \) and \( k \geq 2 \). To prove that \( g_k^T d_k < 0 \) for all \( k \), consider these two cases:

**CASE I:** If \( \beta_k^{RMIL} = \frac{g_k^T (g_k - g_{k-1})}{\|d_{k-1}\|^2} < 0 \), automatically \( \beta_k^{HSMR} \) return to 0 such that \( \beta_k^{SMR} \geq 0 \). When \( \beta_k^{HSMR} = 0 \), it is known that \( g_k^T d_k = -\|g_k\|^2 < 0 \).

**CASE II:** If \( \beta_k^{RMIL} = \frac{g_k^T (g_k - g_{k-1})}{\|d_{k-1}\|^2} \geq 0 \), then, \( \beta_k^{HSMR} \neq 0 \) and can either be \( \beta_k^{SMR} \) or \( \beta_k^{RMIL} \).

Since the line search is exact, it is known that \( g_k^T d_{k-1} = 0 \). Thus, \( g_k^T d_k = -\|g_k\|^2 \) implying \( d_k \) is a sufficient descent direction. Hence, the descent condition holds i.e., \( g_k^T d_k \leq -C\|g_k\|^2 \). The proof is completed.

3.1.2. Global Convergence Properties

From Rivai et al. [3] and Mohamed et al. [4], it is known that \( \beta_k^{SMR} \) and \( \beta_k^{RMIL} \) can be simplified to

\[ 0 \leq \beta_{k+1}^{SMR} \leq \frac{\|g_{k+1}\|^2}{\|d_k\|^2}. \]  

(20)

Case II stated that \( \beta_k^{HSMR} \) and can either be \( \beta_k^{SMR} \) or \( \beta_k^{RMIL} \) if \( \beta_k^{RMIL} = \frac{g_k^T (g_k - g_{k-1})}{\|d_{k-1}\|^2} \geq 0 \). Then, from Rivai et al. [3], Mohamed et al. [4], and Rivaie et al. [19], in the analysis of global convergence properties, the following assumption is needed.

**Assumption 1**

- \( f \) is bounded below on the level set \( R^n \) and is continuous and differentiable in a neighborhood \( N \) of the level set \( \ell = \{ x \in R^n \mid f(x) \leq f(x_0) \} \) at the initial point \( x_0 \).
The gradient \( g(x) \) is Lipschitz continuous in \( N \), so, there exists a constant \( L > 0 \) such that:
\[
\| g(x) - g(y) \| \leq L \| x - y \| \quad \text{for any } x, y \in N.
\]

Under this assumption, the following lemma is obtained, which was proved by Zoutendijk [27].

**Lemma 1:** Suppose that Assumption 1 holds. Consider any CG methods of the form (3) where \( d_k \) is a descent search direction and \( \alpha_k \) satisfies the exact minimization rules. Then the following conditions known as Zoutendijk conditions hold; \[
\sum_{k=0}^{\infty} \frac{(g^T d_k)^2}{\| d_k \|^2} < \infty.
\]

The proof of this lemma can be seen from Dai and Yuan [28]. By using this lemma; the following convergence theorem of the conjugate gradient method can be obtained by using (20).

**Theorem 1:** Suppose that Assumption 1 holds. Consider any CG methods in the form of (3) and (2) where \( \alpha_k \) is obtained by the exact minimization rules. Also, suppose that Assumption 1 and the descent condition hold. Then either \( \lim_{k \to \infty} \| g_k \| = 0 \) or \( \sum_{k=0}^{\infty} \frac{(g^T d_k)^2}{\| d_k \|^2} < \infty \).

**Proof:** By induction, if Theorem 1 is not true then, there exists a constant \( c > 0 \) such that
\[
\| g_k \| \geq c
\]

Rewriting (3) and squaring both sides, we get
\[
\| d_{k+1} \|^2 = (\beta_{k+1})^2 \| d_k \|^2 - 2 \beta_{k+1} \| d_k \| \| g_{k+1} \| \| g_{k+1} \| \| d_{k+1} \| + (\beta_{k+1})^2 \| d_{k+1} \|^2
\]

Using \((g^T d_{k+1})^2\) and dividing both sides,
\[
\frac{\| d_{k+1} \|^2}{(g^T d_{k+1})^2} = \frac{(\beta_{k+1})^2 \| d_k \|^2}{(g^T d_{k+1})^2} \frac{2 \| g_{k+1} \|^2}{\| d_{k+1} \|^2} \frac{\| g_{k+1} \|^2}{\| g_{k+1} \|^2} \frac{1}{\| g_{k+1} \|^2}.
\]

By completing the square, the equation becomes
\[
\frac{(\beta_{k+1})^2 \| d_k \|^2}{(g^T d_{k+1})^2} - \left( \frac{1}{\| g_{k+1} \|^2} + \frac{\| g_{k+1} \|^2}{\| g_{k+1} \|^2} \right)^2 + \frac{1}{\| g_{k+1} \|^2} = \frac{(\beta_{k+1})^2 \| d_k \|^2}{(g^T d_{k+1})^2} + \frac{1}{\| g_{k+1} \|^2}.
\]

Applying (20), yields
\[
\frac{(\| g_{k+1} \|^2)^2}{\| d_k \|^2} - \frac{\| d_k \|^2}{(g^T d_{k+1})^2} + \frac{1}{\| g_{k+1} \|^2} = \frac{(\| g_{k+1} \|^2)^2}{\| d_k \|^2} + \frac{1}{\| d_k \|^2} \leq \frac{1}{\| d_k \|^2} + \frac{1}{\| g_{k+1} \|^2}.
\]

From (23), noting that
\[
\frac{1}{\| d_0 \|^2} = \frac{1}{\| g_0 \|^2},
\]
then,
\[
\frac{|d_k|^2}{(g_k^T d_k)^2} = \frac{1}{|g_0|^2} + \frac{1}{|g_k|^2}.
\]

Hence,
\[
\frac{|d_k|^2}{(g_k^T d_k)^2} \leq \sum_{i=0}^{k} \frac{1}{|g_i|^2} \quad \text{and} \quad \frac{(g_k^T d_k)^2}{|d_k|^2} \geq \frac{c^2}{k}.
\]

Then, from (21) and (23), it follows: \[\sum_{k=0}^{\infty} \frac{(g_k^T d_k)^2}{|d_k|^2} = \infty.\] This contradicts the Zoutendijk [27] condition in Lemma 1. Therefore, the proof is completed.

**Corollary 1:** If \[\sum_{k=0}^{\infty} |d_k|^2 = 0,\] then \[\sum_{k=0}^{\infty} \frac{(g_k^T d_k)^2}{|d_k|^2} < \infty\] holds.

**Proof:** By using contradiction, assume that \[\|g_k\| = c\] and \[\sum_{k=0}^{\infty} |d_k|^2 = \infty.\] For \[\|g_k\| \rightarrow \infty,\] then, \[\frac{1}{\|g_k\|} \rightarrow 0.\]

From (23),
\[
\frac{|d_k|^2}{(g_k^T d_k)^2} \leq \frac{1}{|d_k|^2}
\]
then,
\[
|d_k|^2 \leq \frac{(g_k^T d_k)^2}{|d_k|^2}.
\]
Which leads to,
\[
\sum_{k=0}^{\infty} |d_k|^2 \leq \sum_{k=0}^{\infty} \frac{(g_k^T d_k)^2}{|d_k|^2} \quad \text{and} \quad \infty \leq \sum_{k=0}^{\infty} \frac{(g_k^T d_k)^2}{|d_k|^2}.
\]
This contradicts the Zoutendijk [27] conditions. Hence the corollary holds.

### 3.2. Discussion

This section shows the numerical performance of the new coefficient HSMR compared with its classical combination in (5) and (6). In this research, artificial problems are chosen from the small to large-scale twenty-one test functions as listed in Table 1. The list is considered from Andrei [29]. A large-scaled problem is chosen in order to detect a cynical observer preventing the algorithm being tuned in particular functions [29]. For each of the test functions selected, random initial points are chosen in order to test the global convergence properties along with the robustness of the methods. On the other hand, for each of the random initial points chosen, they are tested on various dimensions from two to thousand dimensions [30], [31]. Points chosen can also be used to test the global convergence properties and the robustness of the methods. Results analyses are based on MATLAB subroutine program on workstation Intel Core i7, 2.2 GHz tested on the number of iterations and central processing time per unit. The stopping criterion is set to \[\|g_k\| \leq 10^{-6},\] where \(\varepsilon = 10^{-6}\). Performance profiles based on Dolan and More [32] are shown graphically in figures below. The results summaries for all SMR, RMIL, and HSMR methods are shown in Table 2.
Performance comparison involving tables are very hard to interpret in order to benchmark methods’ efficiency. Thus, the best way to discuss the performance of each method is by using the performance profile as introduced by Dolan [33]. The \( P_t(t) \) from the performance profile is the fraction of the problem with a ratio performance \( t \). A solver has higher efficiency when its value \( P_t(t) \) is higher. In a set of problem \( P \) and a set of optimization solver \( S \), a performance comparison of the problem \( p \in P \) by a particular algorithm \( s \in S \) is measured. Let, \( t_{p,s} \) be the number of iterations or CPU time required when solving a problem \( p \in P \) with the solver \( s \in S \). The performance ratio is defined by \( r_{p,s} = \frac{t_{p,s}}{\min t_{p,s} : s \in S} \).

From this expression, it is assumed that \( r_{p,s} \in [1, r_M] \), where \( r_M \geq r_{p,s} \) and \( r_{p,s} = r_M \) only when the problem \( p \) is not solved by the solver \( s \). Then, graphically, a graph of \( P_t(t) \) versus \( t \in [1, r_M] \) is plotted.

From Fig. 2, the graph shows that HSMR, SMR, and RMIL are quite identical to each other in terms of their competitiveness and HSMR slightly reach 1 at the top faster than SMR and HSMR. In a graph of performance profile, the smallest performance ratio is 1 and it will be located at the most left of \( t \)-axis, hence, the top curve represents the most efficient method. Though the values displayed in Table 2 may be used to describe the methods’ efficiency, this way of comparison is not very fair since the presence of ‘NAN’ in some problems are not taken into account.
From Fig. 2, the performance profile showed indicates the comparison of each of the coefficient performances in terms of Number of Iterations (NOI) and Central Processing Time per Unit (CPU time) under exact line search. The top left curve indicates the fastest coefficient reaching the solution point while the top right curve shows the ability of the coefficient can solve the test functions used. Based on these curves, it is shown that SMR and HSMR outperform the RMIL under exact line search.

4. Conclusion

In this paper, a hybrid CG method of HSMR method is introduced as a combination of SMR and RMIL. All three methods are compared and the results show that the hybrid version has better performance due to inherit the good characteristics from both SMR and RMIL. The proofs showed that the new method fulfills the convergence properties. The application for these methods can be seen in [33]–[35]. For future works, these methods should be done for inexact line search approach.
